Authors' contributions

This work was carried out in collaboration among all authors. Authors FTN and TD designed the study. Authors JJ, FTN, CND and JPD conducted pharmacological and biochemical studies. Authors RKG, JPD and RNF performed histological and histomorphometry studies. Authors FTN JHD and PDDD have been involved in drafting the manuscript. Authors JHD and JJ performed statistical analyses. Author JJ harvested the plant sample and performed the plant extraction. All authors contributed substantially to the manuscript, read and approved its final version. All authors read and approved the final manuscript.

ABSTRACT

Background: Bone fracture is a condition in which there is a break in the continuity of the bone due to traumatic or pathological factors. Fracture management includes orthopedic, surgical, non-surgical techniques and drug treatments. However, these treatments possess a limitation. Facilitating bone healing process reduce the cost, the time of treatment and is also beneficial for a quick recovery of the patient. The present study aimed to investigate the effect of the mixture aqueous extracts from *Oxalis corniculata* and *Acmella caulirhiza* on the bone formation.

*Corresponding author: E-mail: tsngueguim@yahoo.fr;

Methodology: Wistar female rats were fractured using a drill machine by inserting a drill bit in the femur diaphysis. Fractured animals were subdivided into five groups. One group receiving palm oil, four groups receiving the mixture of plant extracts at the doses of 150, 300, 600 mg/kg or diclofenac at the dose of 357 mg/kg. Substances were given via percutaneous and oral routes for two weeks. At the end of the experimental period, bones were collected and homogenized for the evaluation of the following biochemical parameters: alkaline phosphatase (ALP); reduced glutathione (GSH), nitrites, superoxide dismutase (SOD), interleukin-1 β and interleukin-6. Moreover, histomorphometry of the bone at the fracture site was realized.

Results: Percutaneous treatment with the plant extracts resulted in a significant increase of ALP activity (p<0.05) in fractured rats as compared to the control. The mixture extracts also alleviated the fracture-induced oxidative stress by increasing the concentrations of GSH and nitrites; SOD and catalase activities. Furthermore, the plant extracts improved deregulated cytokines observed in fractured bone. Histopathological examination showed a more pack-like structure with a significant decrease in trabeculae number, trabecular interspace with the increase in the bone thickness.

Conclusion: The mixture aqueous extracts from *Oxalis corniculata* and *Acmella caulirhiza* possesses bone healing effect due to its ability to alleviate oxidative stress, regulate proinflammatory cytokines and improve the structure of the new bone formed.

Keywords: Acmella caulirhiza; cytokines; fracture; histomorphometry; Oxalis corniculata; oxidative stress.

1. INTRODUCTION

Bone tissue is a specialized and dynamic tissue in perpetual renewal that undergoes a constant process of remodeling to accommodate changing mechanical stresses [1]. The broken bone is allowed to regenerate naturally on its own due to a complex process such as cell proliferation and differentiation, factors including growth factors. inflammatorv cvtokines. antioxidants and nutrients. Bone injury implies a secretion of pro-inflammatory cytokines such as tumor necrosis factor-alpha (TNF-α), interleukins (IL-1, IL-6, IL-11, IL-23), bone morphogenetic proteins (BMPs). These molecules act together to stimulate biological process at the fracture site, recruiting macrophages, monocytes, and lymphocytes [2,3]. Till date. fracture management involves several stages: the stabilization of the fracture site, by using inflatable plastic braces and / or radiographic examinations, allowing the orientation of the choice of treatment which can be orthopedic and / or surgical. Drug treatments consist of using osteoinductive (bisphosphonates, synthetic bone morphogenetic proteins) and anti-inflammatory substances [4,5]. The administration of calcium and vitamin D is also considered, with the patient being kept on drugs [6]. In clinical application, these treatments possess limitations. Medicinal plants remain an important source of a primary healthcare mode for around 85 % of the world's population [7]. The use of these plants is also the first material for some pharmaceutical

industries. Thus, about 80 % of all synthetic drugs derived from medicinal plants [8,9]. Considering the powerful pharmacological effect of many plant extracts already shown; several research teams continue to explore the ethnopharmacological data provided by the traditional healers to scientifically demonstrate the veracity of theses biological effects by using experimental models. Our research team, after an ethnopharmacological survey has previously shown а therapeutic effect of some Cameroonian plant extracts on bone fracture [10]. Facilitating bone healing process reduces the cost, the time of treatment and is also beneficial for a quick recovery of the patient. In west Cameroon, traditional healers used plant extracts alone or in combination to manage fractures. Thus, the mixture of powders of Acmella caulirhiza and Oxalis corniculata in palm oil is used in this region for the treatment of bone fractures. Phytochemical constituents of these two plants include compounds such as: β sitosterol, betulin, 4-hydroxybenzoic acid, ethyl gallate, methoxyflavones, apigenin, and 7-O-β-D-glucopyranoside previously isolated from the whole plant of Oxalis corniculata Linn [11-13]; unsaturated alkylamides and spilanthol isolated from Acmella caulirhiza [14-15]. These different possess pharmacocological compounds activities already demonstrated. The antiinflammatory, anti-diabetic. anti-ulcerogenic. antibacterial and antioxidant properties of Oxalis corniculata (Oxalidaceae) have been already shown [16-17]. Apart from diuretic property, antifungal. hepatoprotective, anti-diabetic and effects of Acmella antioxvdant caulirhiza (Asteraceae) [14], the previous research have shown that the ethanol extract of the plant accelerates fracture repair [10]. No scientific data has reported the effect of Oxalis corniculata alone or in combination with Acmella caulirhiza on fracture healing. This study was aimed at providing laboratory validation of bone regenerative action of plants mixture from Acmella caulirhiza and Oxalis corniculata, made in the Cameroonian ethnotraditional practice.

2. MATERIALS AND METHODS

2.1 Plants Materials

Whole plants of Oxalis corniculata and Acmella caulirhiza were harvested at Bafoussam III in the West region of Cameroon in March 2019. Plants were authenticated at the Cameroon National Herbarium in comparison with the specimen voucher N° 8680 / SRF/cam and N° 3307617NC respectively for Oxalis corniculata and Acmella caulirhiza. The whole fresh plants were cleaned, cut into pieces and dried under a shade at room temperature. The decoction was carried out separately by boiling 100 g of the powder in 1.5 L of tap water for 10 min following the traditional healer instructions. The filtrate obtained was dried at 45 °C in drying-cupboard to yield 20 % and 24.14 % respectively of Oxalis corniculata and Acmella caulirhiza extracts: kept at room temperature until use. The dose of the traditional healer was determined and corresponding to 300 mg/kg which was surrounding by the lower (150 mg/kg) and the higher (300 mg/kg) doses. After the preparation of different tested doses, a third of each dose was administrated by percutaneous route, while the two third were given orally as recommended by the practionner.

2.2 Animals

Female rats weighing $250 \pm 20g$ were used in the present study. They were obtained from the animal house of Faculty of Science at the University of Yaoundé I (Cameroon). Animals were submitted to the standard diet established in the laboratory and they received water ad libitum.

2.3 Femoral Drill Hole Injury

All surgical equipment used to induce the fracture were overnight soacked in alcohol to

avoid an eventual infection. A drill hole injury was created as described by Ngueguim et al. [18,19]. Briefly, the front skin of the mid femur in rats under anaesthesia was incised. After splitting the muscle, periosteum was stripped to expose the femoral bone surface. A drill-hole injury was created using a drill machine (Electrex) by inserting a drill bit with a diameter of 1.2 mm in the anterior portion of the diaphysis of one femur [20]. Fractured animals were subdivided into five groups of seven rats treated as follow: one group treated with palm oil (10 mL/kg), another group was treated with sodium diclofenac (357 mg/kg) and three groups were treated with the mixture of the plant extracts at the doses of 150, 300 or 600 mg/kg. In the plant Acmella caulirhiza mixture. and Oxalis corniculata represented respectively 52.5 % and 47.5 % as recommended by the traditional healer. Two groups of unfractured were treated respectively with palm oil (10 mL/kg) or the plant extract at the dose of 600 mg/kg. Different substances were dailv administered bv percutaneous (1/3 of the dose) and oral (2/3 of the same dose) routes for two weeks. At the end experimental period, all animals were of sacrificed under anaesthesia using ketamine (30 mg/kg) and valium mg/kg) (10 via intraperitoneal route. One part of the fractured femur group) was collected (per and refrigerated at -20 °C for bone homogenates using 0.1 M of PBS. The other part of fractured femur was used for histopathological examination and static histomorphometry at the fracture site.

2.4 Assessment of the Mixture Aqueous Extracts from *Acmella caulirhiza* and *Oxalis corniculata* on some Bone Parameters of Oxidative Stress

Bones were carefully removed and the femur has been gently stripped of muscle tissue; the distal portion containing fracture site was weighted (0.2 g). The organ was grounded on a grinding stone, which had beforehand been covered entirely with a hard, transparent, plastic paper. A volume of 3 mL of PBS (phosphate buffer saline) was added to the paste. The bones homogenate were then centrifuged at 3000 rpm at 4 ° C for 30 min. The supernatant obtained was used for biochemical analyses such as alkaline phosphatase, anti-oxidative parameters superoxide including: dismutase (SOD). catalase, reduced glutathione (GSH) and nitrites using commercial kit (Biolab).

2.5 Bone Inflammatory Parameters

Bone homogenate was centrifuged, and supernatant was used for some inflammatory parameter measurements such as IL-1B and II-6 using Quantikine Elisa kits (Germany). Briefly, fifty microliter of assay diluent (RD1-54 and RD1-21 respectively for IL-6 and IL-1β) were added into ELISA pre-coated (antibody II-6 or IL-1ß specific for rat) plates. Then, fifty microliter of the standard or the sample were added to the correspondent well. The mixture was gently homogenized for one minute and the microplates were incubated at 37°C during two hours. Wells were washed five times (with a washer buffer provided by the manufacturer). Moreover, 100 μL of rat specific antibodies anti-II-6 or anti-IL-1β conjugate to horseradish peroxidase were respectively introduced in each well and the mixture was incubated for two hours; the preparation was then washed and incubated with streptavidin for thirty minutes. The enzyme reaction was stopped using sulfuric acid solution. The optical density of each well was measured using a microplate reader. The concentration of each cvtokines was determined from the corresponding calibration curve.

2.6 Histopathological Analysis

Histological analysis at the site of the fracture was assessed by Haematoxilin-Eosin staining method. The bones were conserved in 10 % formalin and demineralized in 10 % HCL solution for 5 days. Isolated femur samples containing the drill hole injury were embedded in paraffin and a thickness of 10 μ m sections were made using a microtome (Reichert-Jung 2030). Photographs of the sections were taken using a digital camera for microscope (DCM 35:350 K Pixels, USB 2.0) aided with appropriate filters.

2.7 Assessment of Static Histomorphometry

The thickness and the number of trabeculae were measured using ImageJ software version 1.49 [21]. The thickness of the trabeculae was carried out by performing twenty measurements per field (four) in each slide. Then the averages were considered.

2.8 Statistical Analysis

Results are expressed as mean ± standard error mean. Statistical significance was determined by

one way analysis of variance followed by the Tukey post-test using Graph pad Prism version 8.0.1 (GraphPad Software, San Diego, California, USA). Differences were considered significant at p < 0.05.

3. RESULTS

3.1 Effects of the Mixture of *Oxalis corniculata* and *Acmella caulirhiza* on Bone Alkaline Phosphatase

Fig. 1 illustrates the effect of the mixture of Oxalis corniculata and Acmella caulirhiza whole plant aqueous extract on bone alkaline phosphatase. Fractured rats showed а significant reduction of ALP activity (p < 0.05) compared to unfractured control rats. The percutaneous administration of the plant extract at the doses of 150 and 300 mg/kg for two weeks provoked a significant increase (p < 0.05) level of ALP activity respectively by 28.62 % and 28.06 % compared fractured to control. No significant change was observed at the dose of 600 mg/kg in fractured and unfractured rats. The administration of diclofenac at the dose of 357 mg/kg to fractured rats induced a significant increase (p < 0.01) of ALP activity.

3.2 Effects of the Mixture of Oxalis corniculata and Acmella caulirhiza on Some Non-enzymatic Oxidative Stress Parameters

Bone injury provoked a significant decrease in reduced glutathione level by 51.31% (p < 0.001) in comparison to unfractured control rats (Fig 2A). The treatment with the plant extracts mixture at the doses of 150 and 300 mg/kg induced a significant increase of reduced glutathione level by 38.28 % (p < 0.01) and 30.32 % (p < 0.05). It was noticed that the level of reduced glutathione was significantly (p < 0.001) low as compared to unfractured rats. In comparison unfractured to rats. the concentration of bone nitrites at the site of fracture was reduced by 39.68 % (p < 0.05) (Fig. 2B). The administration of the extract the dose of 150 mg/kg significantly at increased nitrites concentration by 42.42 % (p < Percutaneous administration 0.05). of the extract at the dose of 600 mg/kg failed to increase both parameters in fractured rats.

3.3 Effects of the Mixture of Oxalis corniculata and Acmella caulirhiza on some Enzymatic Antioxidant Parameters

Enzymatic antioxidant parameters such as SOD and catalase were measured at femoral fracture site two weeks post-fracture (Fig. 3). Fracture induction showed a significant decrease in catalase activity by 72.70 % (p < 0.05) when compared to unfractured rats. However daily percutaneous administration of the plant extracts mixture exhibited a significant increase in catalase activity by 56.18 % (p < 0.05) and 64.14 % (p < 0.01) at the respective doses of 150 mg/kg and 300 mg/kg. The SOD activity was significant decreased in fractured rats (Fig 3B). The plant extract treated groups showed a significant rise in the SOD activity. The increase was by 70.26 % (p < 0.001), 61.49 % (p < 0.01) and 47.90 % (p < 0.05) at the respective doses of 150, 300 mg/kg and 600 mg/kg. Diclofenac used as anti-inflammatory drug failed to correct catalase and SOD activities in fractured rats.

3.4 Effects of the Mixture of Oxalis corniculata and Acmella caulirhiza on some Pro-inflammatory Cytokines Parameters

Two weeks following the fracture, fractured control group showed a significant increase (p < 0.01) rate of IL-1 β by 85.92 % (Fig 4A) and IL-6 by 87.41 % (Fig 4B). The administration of the mixture extracts for two weeks showed a significant reduction of IL-1 β and IL-6 by 82.34 % and 89.29 % at the extract dose of 150 mg/kg; by 75.41 % and 84.41% at the dose of 300 mg/kg. The administration of diclofenac at the dose of 357 mg/kg in the same experimental conditions significantly reduced the rate of IL-1 β and IL-6 by 62.40 % and 80.51 % as compared to the fractured rats.

3.5 Effects of the Plant Extracts Mixture on the Trabeculae Number, Thickness of Trabecular Bone and the Intertrabecular Space

Fig. 5 showed the number, the thickness and the intertrabecular space of new bone formed at the fracture site of treated groups (Fig. 6 A, B & C). The trabeculae number in fractured control increases while the thickness decreases. Fractured animals treated with the extracts mixture exhibited a significant (p < 0.001) decrease in trabecular number by 63.98 %, 55.91 % and 51.30 % respectively at the doses of 150 mg/kg, 300 mg/kg and 600 mg/kg; whereas the thickness of trabecular bone

significantly increased (p < 0.001) by 41.94 (150 mg/kg), 40.89 % (300 mg/kg) and 42.94 % (600 mg/kg) in comparison to fractured untreated control. Moreover, Intertrabecular space elevated in fractured group was significantly reduced in treated groups (p < 0.001) with a pronounced effect at the dose of 150 mg/kg.

3.6 Effects of the Plant Extracts Mixture on Histological Examination

Fractured rats presented a callus characterized by a very loose bone structure with a wider trabecular space as compared to normal bone architecture (Fig 6A). In the treated groups at the doses of 150 and 300 mg/kg (Fig 6B & Fig 6C) trabecular bones were fused with a reduction of trabecular space. The effect was marked at the dose of 150 mg/kg. Fractured animal receiving diclofenac showed a bone structure closed to that of unfractured animals.

4. DISCUSSION

Oxalis corniculata and Acmella caulirhiza are both herbaceous plants used each alone for various ailments. The mixture extracts of these two plants is used in the western region of Cameroon for fracture healing, and no biological activity was studied up to now yet. Therefore, the present study aimed to evaluate the effect of Oxalis corniculata and Acmella caulirhiza aqueous extracts mixture for bone healing effect. The result showed a decrease of alkaline phosphatase activity in fractured rat. This enzyme is an indicator of bone formation, mainly produced by pre-osteoblasts and osteoblasts confirming the proliferation and the differentiation of mesenchymal stem cells [22]. The mixture extracts of plants increased the ALP activity suggesting the probable beneficial effect of these extracts mixture on mesenchymal stem cells and consequently on bone formation. Fracture result to a blood vessels rupture, causing ischemia and hypoxia on surrounding environment [23,24]. These processes could induce the formation of new vessels causing oxygen overload, thus oxidative stress

the Several at fracture site. studies demonstrated that oxidative stress exist during fracture healing process mainly in the stage of callus formation [23,24]. Oxidative stress can be evaluated by measuring the end product of lipid peroxidation malondialdehvde (MDA). nonenzymatic markers such as 8-hydroxy-2deoxyguanosine (8-OHdG), oxidative DNA damage indicator, protein oxidation, ascorbic acid, reduced glutathione, ubiquinone, cysteine and antioxidant enzymes such as superoxide dismutase, gluthatione peroxidase, glutathione transferase [24]. In the present study, the fracture induced a significant decrease in GSH and nitrite levels, catalase and SOD activities. The decrease in GSH level may be due to the overproduction of reactive oxygen species (ROS) and/or an increase in the harmful effects of hydrogen peroxide following the inhibition of glutathione peroxidase activity [25]. The decrease in nitrites level could be due to the cell damage at the fracture site and/or the inhibition of iNOS by inflammatory activity at bone fracture site. While the decrease in catalase and SOD activities is thought to be due to an overproduction of superoxide anion and hydrogen peroxide after reperfusion [26,27]. These results provided the justification of the existence of oxidative stress after a bone hole injury contributing to slowing bone consolidation. It is well known that inflammation response is one stage of fracture healing and during this stage, ROS produced can in turn cause further damage or can exacerbate the stressinflammation cycle characterized by a cascade of events involving the production of cytokines

[23]. In fact, studies have shown that during fracture healing process, inflammatory cells proliferate and migrate to the fracture site, initiate a series of healing reactions [3,28]. The production of cvtokines by inflammatory and immunity cells plays an essential role in the mechanisms of injury. Inhibiting these cytokines with biomedicines reduces inflammation and protects the joint. Among these cytokines are interleukin-1 and interleukin-6 [3]. Osteoblasts and chondroblasts release cytokines within 3 - 7 days following the fracture [26, 29]. However in this study, the level of IL-1 β and IL-6 in fractured rats remained higher than those of unfractured rats suggesting a lower and progressive natural healing process. The significant reduction of IL- 1β and IL-6 very closed to normal value supporting the view that the mixture aqueous extracts from Oxalis corniculata and Acmella caulirhiza accelerates bone healing process. These different effects of the extract could be attributed to the presence of antioxidant and anti-inflammatory compounds in the mixture. In fact, flavonoïds, sterols and terpenoides within Acmella caulirhiza [30]; phenols and tanins within Oxalis corniculata [31] are group of compounds known for their ability to scavenge ROS. These compounds have probably reacted synergically to accelerate bone healing. Several methods are used for assessing skeletal repair including histomorphometry [32,33]. Thus, in this study, the pharmacological effects observed is reinforced by the reduced number of formed trabeculae, their thickness and the trabecular space. This result is strengthening by a fused bone callus observed in histologic

microphotograph. In addition, the reduction of the trabecular space is the consequence of the increase of the thickness of trabeculae attesting a more pack-like structure of new bone formed. The aqueous extracts mixture of Oxalis corniculata and Acmella caulirhiza possesses a double potential: anti-oxidant and antiinflammatory than the reference drug which acts anti-inflammatory. These only as two pharmacological effects of the plant extract mixture could explain the efficacy of the extract. More interesting is that, both plants are safe [34-361 nevertheless, further studies are required to determine the innocuity of the aqueous extracts mixture of these plants.

5. CONCLUSION

In conclusion, bone injury was characterized by a decrease in ALP activity, an increase in oxidative stress accompanied by an increase in cytokine such as IL-1 β and IL-6 with a loose bone structure. The administration of the aqueous extracts mixture of *Oxalis corniculata* and *Acmella caulirhiza* significantly increased ALP activity, improved antioxidant defenses, reduced inflammatory response and bone architecture at fracture site at the effective dose of 150 mg/kg. This bone healing effect observed in the present work was achieved by the antioxidant and antiinflammatory activities of the extract justifying the use of this extract mixture in the management of the fracture.

CONSENT

It is not applicable.

ETHICAL APPROVAL

The procedures followed the principles of laboratory animals use and care of the "European community guidelines (EEC Directive 2010/63/EEC) and were approved by the "Animal Ethical committee" of the Faculty of Science, University of Yaoundé I.
